19 ABSTRACT (Continue on reverse if necessary and identify by block number) The NORSE (Nuclear Optical and Radar System Effects) Code is being developed by DNA as a systems analysis tool. This report describes the local Thermal Equilibrium Emissions data base used by the NORSE code. Graphs of the Weakline and Strongline parameters in the spectral region of 10 cm^{-1} to $10,000\text{ cm}^{-1}$ are presented. A brief description of the band models used by NORSE is given.

PREFACE

This Manual is a graphical compendium of the NORSE LTE infrared data base. The complete NORSE data base is shown. Whenever possible the assumptions used to generate this information have been given. The theoretical background of the NORSE transmission model is briefly discussed.

212 Weak-line parameter for HNO_3 at 300°K	236
213 Weak-line parameter for NO_2	238
214 Inverse line spacing for NO_2	239
215 Weak-line parameter for NO_2 at 200°K	240
216 Weak-line parameter for NO_2 at 300°K	241
217 Weak-line parameter for NO_2 at 500°K	242
218 Weak-line parameter for NO_2 at 750°K	243
219 Weak-line parameter for NO_2 at 1000°K	244
220 Weak-line parameter for NO_2 at 1500°K	245
221 Weak-line parameter for NO_2 at 2000°K	246
222 Weak-line parameter for NO_2 at 3000°K	247
223 Weak-line parameter for NO_2 at 5000°K	248
224 Weak-line parameter for NO_2 at 7000°K	249
225 Strong-line parameter for NO_2 at 200°K	250
226 Strong-line parameter for NO_2 at 300°K	251
227 Strong-line parameter for NO_2 at 500°K	252
228 Strong-line parameter for NO_2 at 750°K	253
229 Strong-line parameter for NO_2 at 1000°K	254
230 Strong-line parameter for NO_2 at 1500°K	255
231 Strong-line parameter for NO_2 at 2000°K	256
232 Strong-line parameter for NO_2 at 3000°K	257
233 Strong-line parameter for NO_2 at 5000°K	258
234 Strong-line parameter for NO_2 at 7000°K	259
235 Weak-line parameter for O_3	261

LIST OF ILLUSTRATIONS (Continued)

Figure	Page
236 Inverse line spacing for O_3	262
237 Weak-line parameter for O_3 at 200°K	263
238 Weak-line parameter for O_3 at 300°K	264
239 Weak-line parameter for O_3 at 500°K	265
240 Weak-line parameter for O_3 at 750°K	266
241 Weak-line parameter for O_3 at 1000°K	267
242 Weak-line parameter for O_3 at 1500°K	268
243 Weak-line parameter for O_3 at 2000°K	269
244 Weak-line parameter for O_3 at 3000°K	270
245 Weak-line parameter for O_3 at 5000°K	271
246 Weak-line parameter for O_3 at 7000°K	272
247 Strong-line parameter for O_3 at 200°K	273
248 Strong-line parameter for O_3 at 300°K	274
249 Strong-line parameter for O_3 at 500°K	275
250 Strong-line parameter for O_3 at 750°K	276
251 Strong-line parameter for O_3 at 1000°K	277
252 Strong-line parameter for O_3 at 1500°K	278
253 Strong-line parameter for O_3 at 2000°K	279
254 Strong line parameter for O_3 at 3000°K	280
255 Strong-line parameter for O_3 at 5000°K	281
256 Strong-line parameter for O_3 at 7000°K	282
257 Weak-line parameter for SO_2	284
258 Inverse line spacing for SO_2	285
259 Weak-line parameter for SO_2 at 200°K	286
260 Weak-line parameter for SO_2 at 300°K	287
261 Weak-line parameter for SO_2 at 500°K	288

LIST OF ILLUSTRATIONS (Continued)

Figure	Page
262 Weak-line parameter for SO_2 at 750°K	289
263 Weak-line parameter for SO_2 at 1000°K	290
264 Weak-line parameter for H_2O	292
265 Inverse line spacing for H_2O	293
266 Weak-line parameter for H_2O at 200°K	294
267 Weak-line parameter for H_2O at 300°K	295
268 Weak-line parameter for H_2O at 500°K	296
269 Weak-line parameter for H_2O at 750°K	297
270 Weak-line parameter for H_2O at 1000°K	298
271 Weak-line parameter for H_2O at 1500°K	299
272 Weak-line parameter for H_2O at 2000°K	300
273 Weak-line parameter for H_2O at 3000°K	301
274 Weak-line parameter for H_2O at 5000°K	302
275 Weak-line parameter for H_2O at 7000°K	303
276 Strong-line parameter for H_2O at 200°K	304
277 Strong-line parameter for H_2O at 300°K	305
278 Strong-line parameter for H_2O at 500°K	306
279 Strong-line parameter for H_2O at 750°K	307
280 Strong-line parameter for H_2O at 1000°K	308
281 Strong-line parameter for H_2O at 1500°K	309
282 Strong-line parameter for H_2O at 2000°K	310
283 Strong-line parameter for H_2O at 3000°K	311
284 Strong-line parameter for H_2O at 5000°K	312
285 Strong-line parameter for H_2O at 7000°K	313
286 Weak-line parameter for AlO	315
287 Inverse line spacing for AlO	316

LIST OF ILLUSTRATIONS (Continued)

Figure	Page
288 Weak-line parameter for AlO at 200°K	317
289 Weak-line parameter for AlO at 300°K	318
290 Weak-line parameter for AlO at 500°K	319
291 Weak-line parameter for AlO at 750°K	320
292 Weak-line parameter for AlO at 1000°K	321
293 Weak-line parameter for AlO at 1500°K	322
294 Weak-line parameter for AlO at 2000°K	323
295 Weak-line parameter for AlO at 3000°K	324
296 Weak-line parameter for AlO at 5000°K	325
297 Weak-line parameter for AlO at 7000°K	326
298 Weak-line parameter for AlO at 10000°K	327
299 Weak-line parameter for AlO at 12000°K	328
300 Weak-line parameter for AlO at 18000°K	329
301 Strong-line parameter for AlO at 200°K	330
302 Strong-line parameter for AlO at 300°K	331
303 Strong-line parameter for AlO at 500°K	332
304 Strong-line parameter for AlO at 750°K	333
305 Strong-line parameter for AlO at 1000°K	334
306 Strong-line parameter for AlO at 1500°K	335
307 Strong-line parameter for AlO at 2000°K	336
308 Strong-line parameter for AlO at 3000°K	337
309 Strong-line parameter for AlO at 5000°K	338
310 Strong-line parameter for AlO at 7000°K	339
311 Strong-line parameter for AlO at 10000°K	340
312 Strong-line parameter for AlO at 12000°K	341
313 Strong-line parameter for AlO at 18000°K	342

LIST OF ILLUSTRATIONS (Continued)

SECTION 1

INTRODUCTION

1.1 DESCRIPTION OF THE DATA.

This manual describes the NORSE LTE (Local Thermodynamic Equilibrium) database including, when possible, the input assumptions used to generate the data. The NORSE LTE data base consists of values for the weak-line parameter (S/d - SOD) and the inverse line spacing ($1/d$ - DEI) arranged by wavenumber, temperature and molecule. This information is used by NORSE for thermal emission calculations.

The NORSE database contains emission information for twenty-six molecules and thirteen temperatures. The spectral range of this data is from 10 cm^{-1} (far infrared) to $100,000\text{ cm}^{-1}$ (visible).

The spectral data presented later in this report represents the NORSE LTE data base 87244.

1.2 DATA SOURCES.

The data sources for this database include: Band model programs, Air Force Geophysical Laboratory Line Atlas, Air Force Weapons Laboratory opacity database and other sources. Some of the information within this database originated over twenty years ago. During that time period the source of the data and the assumptions used to generate the information have been lost. When possible the source of the LTE data and the input assumption, will be presented in sections describing individual molecules.

1.3 LTE DATA BASE.

The LTE data base is stored as an ASCII file at the Los Alamos National Laboratory Central Computing Facility. The data base consists of over 260,000 eighty character lines of information. Further information about the structure and contents of the data base is contained in the NC RSE Manual 4-10 Model Data Files¹.

1.4 FUTURE EFFORTS.

Enhancement and verification of the LTE data base is a continuing effort. The Local Thermal Equilibrium (LTE) data base is updated and reviewed on a regular basis. Work is underway to bring this data in line with current spectroscopic data.

SECTION 2

BACKGROUND²

2.1 TRANSMISSION BAND MODELS.

The presentation in this section has been adapted from a discussion given in reference 2. Given a spectral line atlas it is possible to calculate photon transport along an optical path with varying temperature and pressure. In practice, a line-by-line calculation is impractical because of the large number of lines which need to be considered. To simplify the numerics, various band models have been developed.

Band models differ in their method of treating rotation lines; in fact, a rotational line-by-line reconstruction (or prediction) is often called the "line-by-line model" recognizing that even in the most painstaking predictions, there are assumptions, improper methods of including coupling, etc., which prevent the accurate representation of the actual situation.

A brief review of the different types of band models follows. As an introduction, it can be shown from radiative transfer considerations that the energy, E_a , absorbed through a path length s , in a solid angle Ω and reaching an area A is given by

$$\frac{d^2 E_a}{dA d\Omega} = \int_0^\infty I_\nu^o [1 - \exp(-a_\nu s)] d\nu \quad (1)$$

whereas the energy emitted, E_e , to A by a gas is given by

$$\frac{d^2 E_e}{dA d\Omega} = \int_0^\infty I_\nu^b [1 - \exp(-a_\nu s)] d\nu \quad (2)$$

where I_ν^o is the incident intensity at wavenumber ν , I_ν^b is the Blackbody emission intensity, and a_ν is the line absorption coefficient. It will be assumed that a_ν is zero, except in the small wavenumber interval near to ν_{ij} . For small path lengths, the integrals in Eqns. (1) and (2) will be large only within this narrow interval, so that the integration need only be performed over this interval. Within this interval, I_ν^o and I_ν^b are assumed to be constant, at their value of ν . Then the two equations become

$$\frac{d^2 E_a}{dA d\Omega} = I_{\nu_{ij}}^o \int_0^s [1 - \exp(-a_{\nu_{ij}} s)] d\nu \quad (3)$$

and

$$\frac{d^2 E_e}{dA d\Omega} = I_{\nu_{ij}}^b \int_0^s [1 - \exp(-a_{\nu_{ij}} s)] d\nu \quad (4)$$

where ij indicates the two levels involved in the line transition. The absorbed energy as well as the emitted energy for the line in question are seen to be dependent on the same integral; this integral is called "effective line width" \bar{A}_{ij} , i.e.,

$$\bar{A}_{ij} = \int_0^s [1 - \exp(-a_{\nu_{ij}} s)] d\nu \quad (5)$$

and has the units of ν (cm^{-1}). \bar{A}_{ij} can be interpreted as follows. If $a_{\nu_{ij}}$ is considered infinitely large, and there is no absorption outside this line, \bar{A}_{ij} can be considered as the width of a black line centered at ν_{ij} that produces the identical emission as the actual line.

\bar{A}_{ij} can be evaluated for two limiting cases. If the product $(a_{\nu_{ij}} s)$ is small (i.e., $\ll 1$) an expansion of the exponent in Eqn. (5) gives:

$$1 - \exp(-a_{\nu_{ij}} s) = a_{\nu_{ij}} s - \frac{(a_{\nu_{ij}} s)^2}{2!} + \dots \quad (6)$$

Keeping only the first term, Eqn. (5) becomes

$$\bar{A}_{ij} = s \int_0^{\infty} a_{\nu_{ij}} d\nu \quad (7)$$

where the integral represents the "integrated absorption coefficient." The effective line width is therefore linear with path length, s , regardless of the line profile; a line with this linear behavior is called a "weak-line." [*"Line profiles" arise because the upper and lower energy levels, which determine the energy of a spectral "line", are in reality a distribution of levels; transitions from one distribution (say, the upper) to another distribution (lower) gives rise to a spectral line "profile". Depending on the statistical nature of these distributions, profiles are called Lorentzian, Gaussian, or Voigt (a convolution of Lorentzian and Gaussian). For our purposes, the major cause of Gaussian profiles is Doppler broadening, the term we will use in this work. The importance of line profiles cannot be overemphasized*].

The other limit concerns a large optical path (optically thick). In this limit, $a_{\nu_{ij}} s \gg 1$, the absorption coefficient is written

$$a_{\nu_{ij}} = b_{ij} \int_0^{\infty} a_{\nu_{ij}} d\nu \quad (8)$$

where b_{ij} is the line profile. Using the Lorentz profile for b_{ij} , substituting Eqn. (8) into Eqn. (7) and performing integration and rearrangements, it is found that

$$\bar{A}_{ij} = (2s\gamma_L \int a_{\nu_{ij}} d\nu)^{1/2}, \quad (9)$$

where γ_L is the Lorentzian width at half-maximum. Thus, the "strong-line" approximation leads to an absorption varying with the square root of the path length (s) in contrast to the "weak-line" approximation where it varies linearly with s .

In a similar manner, an "effective band width", \bar{A}_e can be defined as

$$\bar{A}_e = \int_{band} [1 - \exp(-a_{\nu_y} s)] d\nu \quad (10)$$

The boundaries of the band can be defined as the wavenumber interval outside of which there is only a predetermined fractional contribution to \bar{A}_e . As the path length increases, the width of the wavenumber interval increases slowly due to absorption taking place in the wings of the line profiles (the profiles are bell shaped). Note that \bar{A}_e for the band is the sum of the \bar{A}_y for all the lines that constitute the band, only if all the \bar{A}_y do not overlap. Since the lines overlap, each line absorbs less energy than if there were no overlap.

In the derivation of appropriate band models, simplified forms of the absorption coefficient a_{ν} must be devised. The two more common types of band models are the Regular and Random Band Models.

The most familiar of the Regular techniques is due to Elsasser. In this model, the individual lines all have the same profile, the same height and the same spacing. Elsasser's approach uses the Lorentz line profile (the Doppler and Voigt profiles may also be used). The absorption coefficient at a specified wavenumber is calculated by adding all the contributions from neighboring lines. If the specified position is ν_o , the distance of the centers of the other lines from the specified wavenumber ν_o is $|\nu_o - 0|$, $|\nu_o - d|$, $|\nu_o - 2d|$, Summing the contributions results in:

$$a(\nu_o) = \frac{\int a_L d\nu}{2\pi} \sum_{-\infty}^{\infty} \frac{\gamma_L}{\frac{\gamma_L^2}{4} + (\nu_o - nd)^2} \quad (11)$$

where $a(\nu_o)$ is the absorption coefficient at the specified wavenumber (ν_o), $\int a_L d\nu$ is the integrated absorption coefficient for each line, n is the number of lines contributing, d is the spacing between adjacent peaks and γ_L is the Lorentzian width.

This function is substituted in Eqn. (7). By using the "weak-line" and "strong-line" limits, analytic solutions are practical, otherwise numerical methods are necessary.

The Random (or Statistical) band model uses a statistical array of individual lines. In this case, there can be a random spacing of identical or dissimilar lines. In order to apply this model, probability distributions of line strengths and positions must be assumed. Once the nature of a line, and its position, are chosen, the effective band width \bar{A}_ℓ is calculated from Eqn. (10). Note that \bar{A}_ℓ depends on the line spacing, the width of the line profile, and the integrated absorption. Since these parameters rely on temperature and density, it is necessary to know how they change with temperature and pressure.

2.2 BAND MODEL PARAMETERS.

An important source of radiation from low-altitude fireballs is thermal emission due to equilibrium processes in the hot gas. The magnitude of the radiation is determined by the temperature and the optical absorption properties of the fireball. For infrared wavelengths, the vibrational-rotational bands of

molecular species are major contributors to thermal emission. Particularly important emitters in a fireball are CO_2 , CO , NO and NO^+ . Other potential infrared emitters include O_3 , NO_2 , N_2O , H_2O , OH and metal oxides (MeO).

A procedure has been developed for the NORSE³ code that uses band absorption models to calculate fireball thermal emission. These models require the fireball sight-path length, the average pressure over the path, an isothermal temperature of the emitting gas, and the population of species in the fireball. The spectral radiance of the path length is then calculated as a function of wavenumber. The models described in Section 2.1 include:

- o Elsasser model. This model is appropriate for a band of lines with uniform intensity, width and spacing.
- o Random Elsasser model. This model assumes n randomly superimposed Elsasser bands. The limit n corresponds to the statistical model, while $n = 1$ corresponds to the Elsasser model.
- o Statistical model. This model assumes lines with arbitrary strength and width distributions, and random spectral frequency.

For molecules of the asymmetrical top (three moments of inertia, all unequal) form, such as H_2O , the rotational structure is quite irregular, and the statistical model is clearly preferred. Symmetric top (rotor) molecules, such as diatomic or linear polyatomic species, have more regular rotational structures. Such a structure is best described by the Elsasser or random Elsasser models for lower temperatures. At elevated temperatures, many such regular bands will overlap. If the number of bands is $n > 10$, there is little difference between the predictions of the random Elsasser and statistical models. Since the statistical model offers the advantage of rapid calculation, and requires a minimum number of parameters to be determined from often scanty data, it is used in the fireball thermal emission model.

In many situations, lines show both Doppler and Lorentz profiles characterized by broadening widths denoted by γ_D and γ_L , respectively. If $\gamma_L \gg \gamma_D$, the absorption predicted by a pure Lorentz line shape is an excellent approximation. The corresponding approximation does not hold for $\gamma_D \gg \gamma_L$, however. In this case, the center of the line will reflect the Doppler profile, while the wings will reflect the Lorentz shape. For small path length, the absorption is well approximated by a pure Doppler line shape. For larger path lengths absorption by the line wings will dominate, so the Lorentz profile is needed.

Stephens⁴ discusses the details of the transmission model. Of interest herein is the fact that in either limit of Doppler or Lorentz shapes, the value of transmission over an optical path of varying temperature, composition, and pressure (affecting the Lorentz profile) can be reduced to functions of γ_L, γ_D , pressure, and so-called weak-line parameters, average line strength, SOD, and effective inverse line spacing, DEI, for individual species. For temperature T and wavenumber ν

$$\text{SOD}(T, \nu) = \sum_i S_i / \Delta \nu \quad (12)$$

$$\text{DEI}(T, \nu) = \left[\sum_i (S_i)^{1/2} / \Delta \nu \right]^2 / \text{SOD}(T, \nu) \quad (13)$$

where $\Delta \nu$ refers to a small wavenumber interval within which there are a limited number of individual quantum mechanical lines of strength S_i .

Thus, calculations of radiation transport are reduced to calculations involving the weak-line parameters SOD and DEI which approximate molecular absorption processes as a function of energy and temperature.

SECTION 3 SAMPLE CALCULATIONS

A sample transmissivity calculation for CO₂ gas in LTE is presented. The data used for this calculation are a subset of the CO₂ data presented in section 5.2 of this report. For simplicity, only data for the 626 (the 626 label denotes the ¹⁶O-¹²C-¹⁶O molecule) isotopic species of carbon dioxide will be used. The temperature, path length, and mole fraction for the absorbing CO₂ gas are chosen to match the experimental conditions as reported.⁵ This exercise will show how the data contained in this volume may be used to predict transmissivity and emissivities using the statistical band model approach.

The transmissivity predicted by various forms of the statistical band model is given by:

$$\tau = \exp[-F(x)(2\pi\gamma_L/d_\nu)] \quad (14)$$

where the curve of growth for the particular model is defined as, $-\ln(\tau)$. The variable x is defined here as:

$$x = (S/d)_\nu u(2\pi\gamma_L/d_\nu)^{-1} \quad (15)$$

where

$$\begin{aligned} \gamma_L & \text{ is the full width at half maximum for a single line with} \\ & \text{Lorentzian shape} \\ \gamma_L & = \gamma_L^o (T_o/T)^\eta \end{aligned} \quad (16)$$

d_ν is the mean line spacing

$(S/d)_w$ is the weak-line parameter

u is related to the number of absorber/emitters

$$u = LX P(T_o/T) \quad (17)$$

where X is the mole fraction of the absorbing/emitting species, P is the pressure, T is the temperature, L is the path length and η is an empirical parameter which is usually about 0.5.

Here it is assumed that all lines have the Lorentz shape and equal widths. The function $F(x)$ is determined by the distribution of line strengths. For example, the probability distribution

$$P(S) \propto (1/S) \exp (-S/S_o) \quad (18)$$

results in

$$F(x) = (1/\pi)[(1+2\pi x)^{1/2} - 1] \quad (19)$$

As $x \rightarrow 0$ the function $F(x)$ becomes proportional to x and the curve of growth is said to be in the linear (weak-line) region. The square root (strong-line) region of the curve of growth obtains when $x \rightarrow \infty$. The curve of growth or $F(x)$ is then proportional to $(x)^{1/2}$. Different choices of the distribution function $P(S)$, will result in the same form for the curve of growth (or $F(x)$) for the asymptotic regions. However, for intermediate values of u (where $x \approx 1$) the various curve of growth functions will be different, with the exponential S^{-1} probability distribution having the largest change between the two asymptotic forms⁶.

The statistical curve of growth which results from the distribution function given in Eqn. 18 is assumed and predictions are made of the transmissivity for a

given optical depth and temperature. In Figure 1 the weak-line parameter as a function of wavenumber is plotted for the 626 isotopic species of the CO_2 molecule for a temperature of $T = 292^\circ\text{K}$. The weak-line parameter is the absorption coefficient for the linear region of the curve of growth. Note the strong P and R branch lobes from the ν_3 fundamental transition located about the band center near 2350 cm^{-1} .

Figure 1. Weak-line parameter for 626 CO_2 .

In Figure 2 the inverse line spacing parameter is displayed as a function of wavenumber for a temperature $T = 292^\circ \text{K}$. The two band model parameters listed in this report are the weak-line parameter $(S/d)_v$ and the strong-line parameter used by Malkmus⁷. The strong line parameter is related to the inverse line spacing parameter by

$$A = (S/d)_v (2\pi\gamma_L/d_v)^{-1} = x/u \quad (20)$$

Figure 2. Inverse line spacing for 626 CO₂.

The weak-line and inverse line spacing parameters are input to the statistical model (Eqn. 14) with the optical conditions of a homogenous sample of gas at a temperature of $T = 292$ °K. The path length is 9.84 cm and the total pressure of the gas is 0.6128 atm, with the mole fraction for CO_2 , $\chi = 0.0230$. The statistical band model gives the transmissivity shown in Figure 3. This predicted transmissivity curve agrees with recent experimental data taken under the same conditions⁵.

Figure 3. Transmittance for 626 CO_2 .

SECTION 4

DIATOMIC MOLECULES

Local thermal equilibrium emission spectra for all diatomic molecules within the spectral range $10 - 10,000 \text{ cm}^{-1}$ have been computed using the DiAtomic Thermal Emissions (DATE) code⁸. In the case of certain molecules, NO, N_2 , N_2^+ and O_2 , data available in the spectral range $5,000 - 100,000 \text{ cm}^{-1}$ was obtained from the VisiDyne Corporation using a database developed by the Air Force Weapons Laboratory (AFWL) in the late sixties and used by the RADiation FLOW (RADFLO) code.

The band strengths given in this section are listed in $\text{cm}^{-2} \text{ atm}^{-1}$ at STP.

4.1 CARBON MONOXIDE (CO).

Data for the CO molecule in the spectral range 10 - 12,000 cm^{-1} has been computed using the DATE code.

4.5 OXYGEN (O₂).

The local thermal equilibrium emission spectra for the Oxygen molecule was calculated by VisiDyne Corporation* using an Air Force Weapons Laboratory opacity data base developed in the late sixties. Data for the weak-line parameter for O₂ in the visible region (5,000 cm⁻¹ - 100,000 cm⁻¹) is available. There is no inverse line spacing information available for this molecule.

Data Source:

*H. Smith, T. Keneshea, VisiDyne Corporation, private communication (1986).

SECTION 5

POLYATOMIC MOLECULES

The local thermal equilibrium emission spectra for polyatomics have been computed from a variety of sources including Triatomic Thermal Emission code (TATE), Air Force Geophysical Laboratory Line Atlas and the Air Force Weapons Laboratory Opacity Database.

5.1 AMMONIA (NH_3).

The local thermal equilibrium emission spectra for Ammonia has been developed from the Air Force Geophysical Laboratory line atlas for 200, 300, 500, 750, 1000 °K.

The NH_3 molecule has been included within the NORSE LTE data base because of its contribution to ambient atmospheric absorption. The inclusion of accurate parameters for this species above 1000 °K is felt to be of low priority.

Figure 146. Weak-line parameter for NH_3 at 750°K .

Figure 147. Weak-line parameter for NH_3 at 1000°K .

5.2 CARBON DIOXIDE (CO₂).

The weak-line and inverse line-spacing parameters for the eight most abundant isotopic species of CO₂ were calculated using the LTE smeared-band model code LINTRA^{*}. The model requires band strengths and molecular constants for the contributing transitions; these constants were obtained from the Air Force Geophysical Laboratory[†]. Theoretical calculations for excited bands of the 626 isotopic species of CO₂ were obtained from VisiDyne[‡]. The smeared band model correctly accounts for the increased population of the rotational states with increasing temperature.

These band model parameters were calculated for each wavenumber between 100 cm⁻¹ and 10,000 cm⁻¹ and then averaged to obtain the required resolution for the NORSE optics database. The temperatures at which these calculations were performed were 200, 300, 500, 750, 1000, 1500, 2000, 3000, 5000, 7000, 10000, 12000, 18000 °K. The band model parameters calculated for temperatures much above 1500 °K are deficient due to the lack of essential experimental and theoretical data.

5.4 METHANE (CH_4).

Local thermal equilibrium emission spectra for Methane has been developed from the Air Force Geophysical Laboratory line atlas for 200, 300, 500, 750, 1000 °K.

The CH_4 molecule has been included within the NORSE LTE data base because of its contribution to ambient atmospheric absorption. The inclusion of accurate parameters for this species above 1000 °K is felt to be of low priority.

5.5 NITRIC ACID (HNO_3).

The local thermal equilibrium emission spectra for Nitric Acid has been developed from the 1982 Air Force Geophysical Laboratory Line Atlas for 300 °K.

The HNO_3 molecule has been included within the NORSE LTE data base because of its contribution to ambient atmospheric absorption. The inclusion of accurate parameters for this species at other temperatures is felt to be of low priority.

Figure 210. Weak-line parameter for HNO_3 .

Figure 211. Inverse line spacing for HNO_3 .

Figure 212. Weak-line parameter for HNO₃ at 300°K.

5.6 NITROGEN PEROXIDE (NO₂).

The local thermal equilibrium emission spectra for Nitrogen Peroxide was taken from the Roscoe IR database for the spectral region $< 5,000 \text{ cm}^{-1}$. In the spectral region of 5,000 to 100,000 cm^{-1} the data was developed by the VisiDyne Corporation^{||} using a Air Force Weapons Laboratory database developed in the late sixties.

The calculation of the LTE NO₂ curves is discussed in ROSCOE Manual Volume 28*. The calculations ($< 5,000 \text{ cm}^{-1}$) were performed with the TATE Code[†].

5.9 WATER (H₂O).

The local thermal equilibrium emission spectra for H₂O was taken from the ROSCOE LTE data base.

Low temperature (200, 300, 500 °K) H₂O data was derived from the Air Force Geophysical Laboratory Line Atlas*. For temperatures above 500 °K the curves were extracted from the WOE fireball LTE parameters† except in the spectral region 2000 - 5000 cm⁻¹ where ROSCOE-IR results were used. Both the WOE high temperature data and the ROSCOE-IR data are based on measurements performed at Convair‡.

APPENDIX B

GLOSSARY

NORSE	<u>N</u> uclear and <u>O</u> ptical <u>R</u> adar and <u>S</u> ystems <u>E</u> ffects code.
LTE	<u>L</u> ocal <u>T</u> hermal <u>E</u> quilibrium.
DEI	Inverse line spacing.
SOD	<u>S</u> trength <u>O</u> ver line spacing (<u>D</u> istance).
RADFLO	<u>R</u> ADiation <u>F</u> LOW Code.
LINTRA	<u>L</u> INear <u>T</u> RIAtomic smeared band model.
WOE	<u>W</u> eapons <u>O</u> ptical <u>E</u> ffects code.
TATE	<u>T</u> RIAtomic <u>T</u> hermal <u>E</u> missions code.
STP	<u>S</u> tandard <u>T</u> emperature and <u>P</u> ressure.

APPENDIX C **LIST OF SYMBOLS**

A	Area
A	Malkmus strong-line parameter
A_L	Effective band width
\bar{A}_{ij}	Effective line width
a_ν	Line absorption coefficient
$a_{\nu ij}$	Line absorption coefficient where ij indicates the upper and lower levels involved in the line transition
b_{ij}	Line profile
E_a	Energy absorbed
E_e	Energy emitted
I_ν	Intensity at energy ν
I_ν^b	Blackbody emission intensity, at energy ν
P	Pressure
$P(S)$	Probability distribution function
T	Temperature, Absolute
s	Path length
u	Adjusted path length
x	Mole fraction
γ_d	Doppler width
γ_L	Lorentzian width
ν	Energy
Ω	Solid angle

LIST OF SYMBOLS (Continued)

ω_e	Spectroscopic constant
$\omega_e x_e$	Spectroscopic constant
α_e	Spectroscopic constant
B_e	Spectroscopic constant
A_e	Spectroscopic constant
S_{10}	Band Strength 1-0 transition
S_{20}	Band Strength 1-0 transition
S_{30}	Band Strength 1-0 transition
γ_e	Lorentz Line Width
